

Package ‘discretization’

October 13, 2022

Type Package

Title Data Preprocessing, Discretization for Classification

Version 1.0-1.1

Date 2010-12-02

Author HyunJi Kim

Maintainer HyunJi Kim <polaris7867@gmail.com>

Description A collection of supervised discretization algorithms. It can also be grouped in terms of top-down or bottom-up, implementing the discretization algorithms.

discretization-package

Data preprocessing, discretization for classification.

Description

This package is a collection of supervised discretization algorithms. It can also be grouped in terms of top-down or bottom-up, implementing the discretization algorithms.

Details

Package:	discretization
Type:	Package
Version:	1.0-1
Date:	2010-12-02
License: GPL LazyLoad:	yes

 ameva

 Auxiliary function for Ameva algorithm

Description

This function is required to compute the ameva value for Ameva algorithm.

Usage

ameva(tb)

Arguments

tb a vector of observed frequencies, $k * l$

Details

This function implements the Ameva criterion proposed in Gonzalez-Abril, Cuberos, Velasco and Ortega (2009) for Discretization. An autonomous discretization algorithm(Ameva) implements in `disc.Topdown(data,method=1)` It uses a measure based on chi^2 as the criterion for the optimal discretization which has the minimum number of discrete intervals and minimum loss of class variable interdependence. The algorithm finds local maximum values of Ameva criterion and a stopping criterion.

Ameva coefficient is defined as follows:

$$Ameva(k) = \frac{\chi^2(k)}{k * (l - 1)}$$

for $k, l \geq 2$, k is a number of intervals, l is a number of classes.

This value calculates in contingency table between class variable and discrete interval, row matrix representing the class variable and each column of discrete interval.

Value

val numeric value of Ameva coefficient

Author(s)

HyunJi Kim <polaris7867@gmail.com>

References

Gonzalez-Abril, L., Cuberos, F. J., Velasco, F. and Ortega, J. A. (2009) Ameva: An autonomous discretization algorithm, *Expert Systems with Applications*, **36**, 5327–5332.

Examples

```
##--Ameva criterion value
a=c(2,5,1,1,3,3)
m=matrix(a,ncol=3,byrow=TRUE)
ameva(m)
```

cacc

Auxiliary function for CACC discretization algorithm

Description

This function is required to compute the cacc value for CACC discretization algorithm.

Usage

```
cacc(tb)
```

Arguments

tb a vector of observed frequencies

Details

The Class-Attribute Contingency Coefficient(CACC) discretization algorithm implements in `disc.Topdown(data,method=2`

The cacc value is defined as

$$cacc = \sqrt{\frac{y}{y + M}}$$

for

$$y = \chi^2 / \log(n)$$

M is the total number of samples, n is a number of discretized intervals. This value calculates in contingency table between class variable and discrete interval, row matrix representing the class variable and each column of discrete interval.

Value

val numeric of cacc value

Author(s)

HyunJi Kim <polaris7867@gmail.com>

References

m=matrix(a,ncol=3,byrow=TRUE)
cacc(m)
```

caim

Auxiliary function for caim discretization algorithm

Description

This function is required to compute the CAIM value for CAIM iscretization algorithm.

Usage

```
caim(tb)
```

Arguments

tb a vector of observed frequencies

Details

The Class-Attribute Interdependence Maximization(CAIM) discretization algorithm implements in `disc.Topdown(data,method=1)`. The CAIM criterion measures the dependency between the class variable and the discretization variable for attribute, and is defined as :

$$CAIM = \frac{\sum_{r=1}^n \frac{max_r^2}{M_{+r}}}{n}$$

for $r = 1, 2, \dots, n$, max_r is the maximum value within the r th column of the quanta matrix. M_{+r} is the total number of continuous values of attribute that are within the interval(Kurgan and Cios (2004)).

caim(m)
```

chi2

Discretization using the Chi2 algorithm

Description

This function performs Chi2 discretization algorithm. Chi2 algorithm automatically determines a proper Chi-square(χ^2) threshold that keeps the fidelity of the original numeric dataset.

Usage

```
chi2(data, alp = 0.5, del = 0.05)
```

Arguments

data	the dataset to be discretize
alp	significance level; α
del	$Inconsistency(data) < \delta$, (Liu and Setiono(1995))

Details

The Chi2 algorithm is based on the χ^2 statistic, and consists of two phases. In the first phase, it begins with a high significance level(sigLevel), for all numeric attributes for discretization. Each attribute is sorted according to its values. Then the following is performed: **phase 1.** calculate the χ^2 value for every pair of adjacent intervals (at the beginning, each pattern is put into its own interval that contains only one value of an attribute); **phase 2.** merge the pair of adjacent intervals with the lowest χ^2 value. Merging continues until all pairs of intervals have χ^2 values exceeding the parameter determined by sigLevel. The above process is repeated with a decreased sigLevel until an *inconsistency rate*(δ), `incon()`, is exceeded in the discretized data(Liu and Setiono (1995)).

Value

cutp	list of cut-points for each variable
Disc.data	discretized data matrix

Author(s)

HyunJi Kim <polaris7867@gmail.com>

#--discretized dataset using Chi2 algorithm
chi2(iris,0.5,0.05)$Disc.data
```

`chiM`*Discretization using ChiMerge algorithm*

Description

This function implements ChiMerge discretization algorithm.

Usage

```
chiM(data, alpha = 0.05)
```

Arguments

<code>data</code>	numeric data matrix to discretized dataset
<code>alpha</code>	significance level; α

Details

The ChiMerge algorithm follows the axis of bottom-up. It uses the χ^2 statistic to determine if the relative class frequencies of adjacent intervals are distinctly different or if they are similar enough to justify merging them into a single interval (Kerber, R. (1992)).

Value

<code>cutp</code>	list of cut-points for each variable
<code>Disc.data</code>	discretized data matrix

Author(s)

HyunJi Kim <polaris7867@gmail.com>

References

Kerber, R. (1992). ChiMerge : Discretization of numeric attributes, *In Proceedings of the Tenth National Conference on Artificial Intelligence*, 123–128.

```

chiSq

Auxiliary function for discretization using Chi-square statistic

Description

This function is required to perform the discretization based on Chi-square statistic(CACC, Ameva, ChiMerge, Chi2, Modified Chi2, Extended Chi2).

Usage

```
chiSq(tb)
```

Arguments

tb a vector of observed frequencies

Details

The formula for computing the χ^2 value is

$$\chi^2 = \sum_{i=1}^2 \sum_{j=1}^k \frac{(A_{ij} - E_{ij})^2}{E_{ij}}$$

k = number of (no.) classes, A_{ij} = no. patterns in the i th interval, j th class, R_i = no. patterns in the j th class = $\sum_{j=1}^k A_{ij}$, C_j = no. patterns in the j th class = $\sum_{i=1}^2 A_{ij}$, N = total no. patterns = $\sum_{i=1}^2 R_i$, E_{ij} = expected frequency of A_{ij} = $R_i * C_j / N$. If either R_i or C_j is 0, E_{ij} is set to 0.1. The degree of freedom of the χ^2 statistic is on less the number of classes.

Value

val χ^2 value

```

cutIndex

Auxiliary function for the MDLP

Description

This function is required to perform the Minimum Description Length Principle.md1p

Usage

```
cutIndex(x, y)
```

Arguments

x	a vector of numeric value
y	class variable vector

Details

This function computes the best cut index using entropy

Author(s)

HyunJi Kim <polaris7867@gmail.com>

disc.Topdown	<i>Top-down discretization</i>
--------------	--------------------------------

Description

This function implements three top-down discretization algorithms(CAIM, CACC, Ameva).

Usage

```
disc.Topdown(data, method = 1)
```

Arguments

data	numeric data matrix to discretized dataset
method	1: CAIM algorithm, 2: CACC algorithm, 3: Ameva algorithm.

Value

cutp	list of cut-points for each variable(minimum value, cut-points and maximum value)
Disc.data	discretized data matrix

Author(s)

extendChi2

Discretization of Numeric Attributes using the Extended Chi2 algorithm

Description

This function implements Extended Chi2 discretization algorithm.

Usage

```
extendChi2(data, alp = 0.5)
```

Arguments

data	data matrix to discretized dataset
alp	significance level; α

Details

In the extended Chi2 algorithm, inconsistency checking ($InConCheck(data) < \delta$) of the Chi2 algorithm is replaced by the lease upper bound $\xi(Xi())$ after each step of discretization ($\xi_{discretized} < \xi_{original}$). It uses as the stopping criterion.

Value

cutp	list of cut-points for each variable
Disc.data	discretized data matrix

findBest*Auxiliary function for top-down discretization*

Description

This function is required to perform the `disc.Topdown()`.

Usage

```
findBest(x, y, bd, di, method)
```

Arguments

x	a vector of numeric value
y	class variable vector
bd	current cut points
di	candidate cut-points
method	each method number indicates three top-down discretization. 1 for CAIM algorithm, 2 for CACC algorithm, 3 for Ameva algorithm.

incon	<i>Computing the inconsistency rate for Chi2 discretization algorithm</i>
-------	---

Description

This function computes the inconsistency rate of dataset.

Usage

```
incon(data)
```

Arguments

data dataset matrix

Details

The inconsistency rate of dataset is calculated as follows: (1) two instances are considered inconsistent if they match except for their class labels; (2) for all the matching instances (without considering their class labels), the inconsistency count is the number of the instances minus the largest number of instances of class labels; (3) the inconsistency rate is the sum of all the inconsistency counts divided by the total number of instances.

Value

inConRate the inconsistency rate of the dataset

Author(s)

HyunJi Kim <polaris7867@gmail.com>

`mergeCols`*Auxiliary function for performing discretization using MDLP*

Description

This function merges the columns having observation numbers equal to 0, required to perform the minimum discription length principle.

Usage

```
mergeCols(n, minimum = 2)
```

Arguments

<code>n</code>	table, column: intervals, row: variables
<code>minimum</code>	min # observations in col or row to merge

Author(s)

HyunJi Kim <polaris7867@gmail.com>

See Also

[cutPoints](#), [ent](#), [cutIndex](#), [mdlStop](#), [mylog](#), [mdlp](#).

`modChi2`*Discretization of Neneric Attributes using the Modified Chi2 method*

Description

This function implements the Modified Chi2 discretization algorithm.

Usage

```
modChi2(data, alp = 0.5)
```

Arguments

<code>data</code>	numeric data matrix to discretized dataset
<code>alp</code>	significance level, α

Details

In the modified Chi2 algorithm, inconsistency checking ($InConCheck(data) < \delta$) of the Chi2 algorithm is replaced by maintaining the level of consistency L_c after each step of discretization ($L_{c-discretized} < L_{c-original}$). this inconsistency rate as the stopping criterion.

Value

cutp	list of cut-points for each variable
Disc.data	discretized data matrix

Xi *Auxiliary function for performing the Extended Chi2 discretization algorithm*

Description

This function is the ξ , required to perform the Extended Chi2 discretization algorithm.

Usage

```
Xi(data)
```

Arguments

<code>data</code>	data matrix
-------------------	-------------

Details

The following equality is used for calculating the least upper bound(ξ) of the data set(Chao and Jyh-Hwa (2005)).

$$\xi(C, D) = \max(m_1, m_2)$$

where C is the equivalence relation set, D is the decision set, and $C^* = \{E_1, E_2, \dots, E_n\}$ is the equivalence classes. $m_1 = 1 - \min\{c(E, D) | E \in C^* \text{ and } 0.5 < c(E, D)\}$, $m_2 = 1 - \max\{c(E, D) | E \in C^* \text{ and } c(E, D) < 0.5\}$.

$$c(E, D) = 1 - \frac{\text{card}(E \cap D)}{\text{card}(E)}$$

card denotes set cardinality.

Value

Xi numeric value, ξ
